Variables

Basic R

Introduction to R for Public Health Researchers

Getting Started

- You should have the latest version of R installed!
- Open R Studio
- Files -> New -> R Script
- Save the blank R script as "day1.R" in a directory of your choosing
- Add a comment header

Commenting in Scripts

Add a comment header to day1.R:# is the comment symbol

Explaining output on slides

In slides, a command (we'll also call them code or a code chunk) will look like this

```
print("I'm code")
```

```
[1] "I'm code"
```

And then directly after it, will be the output of the code. So print("I'm code") is the code chunk and [1] "I'm code" is the output.

R. as a calculator

```
2 + 2
```

[1] 4

```
2 * 4

[1] 8
2 ^ 3
```

[1] 8

Note, when you type your command, R inherently thinks you want to print the result.

R as a calculator

- The R console is a full calculator
- Try to play around with it:
 - -+,-,/,* are add, subtract, divide and multiply
 - ^ or ** is power
 - parentheses (and) work with order of operations

R as a calculator

```
2 + (2 * 3)^2
[1] 38
(1 + 3) / 2 + 45
[1] 47
```

R as a calculator

[1] 4

Try evaluating the following:

- 2 + 2 * 3 / 4 -3 • 2 * 3 / 4 * 2 • 2^4 - 1
- ____
- You can create variables from within the R environment and from files on your computer
- R uses "=" or "<-" to assign values to a variable name
- Variable names are case-sensitive, i.e. X and x are different

```
x = 2 # Same as: x <- 2
x
[1] 2
x * 4
[1] 8
x + 2</pre>
```

R variables

- The most comfortable and familiar class/data type for many of you will be data.frame
- You can think of these as essentially Excel spreadsheets with rows (usually subjects or observations) and columns (usually variables)

R variables

- data.frames are somewhat advanced objects in R; we will start with simpler objects;
- Here we introduce "1 dimensional" classes; these are often referred to as 'vectors'
- Vectors can have multiple sets of observations, but each observation has to be the same class.

```
class(x)
```

```
[1] "numeric"
y = "hello world!"
print(y)

[1] "hello world!"
class(y)

[1] "character"
```

R variables

Try assigning your full name to an R variable called name

R variables

Try assigning your full name to an R variable called name

```
name = "John Muschelli"
name
```

[1] "John Muschelli"

The 'combine' function

The function c() collects/combines/joins single R objects into a vector of R objects. It is mostly used for creating vectors of numbers, character strings, and other data types.

```
x <- c(1, 4, 6, 8)
x
[1] 1 4 6 8
class(x)
```

The 'combine' function

[1] "numeric"

Try assigning your first and last name as 2 separate character strings into a single vector called name2

The 'combine' function

Try assigning your first and last name as 2 separate character strings into a length-2 vector called name2

```
name2 = c("John", "Muschelli")
name2
```

```
[1] "John"
                "Muschelli"
```

R variables

length(): Get or set the length of vectors (including lists) and factors, and of any other R object for which a method has been defined.

```
length(x)
[1] 4
У
[1] "hello world!"
length(y)
[1] 1
```

R variables

What do you expect for the length of the name variable? What about the name2 variable?

What are the lengths of each?

R variables

What do you expect for the length of the name variable? What about the name2 variable?

What are the lengths of each?

```
length(name)
[1] 1
length(name2)
[1] 2
```

R variables

You can perform functions to entire vectors of numbers very easily.

```
x + 2
[1] 3 6 8 10
x * 3
[1] 3 12 18 24
```

```
x + c(1, 2, 3, 4)
```

[1] 2 6 9 12

R variables

But things like algebra can only be performed on numbers.

```
> name2 + 4
[1] Error in name2 * 4 : non-numeric argument
to binary operator
```

R variables

And save these modified vectors as a new vector.

```
y = x + c(1, 2, 3, 4)
```

```
[1] 2 6 9 12
```

Note that the R object y is no longer "Hello World!" - It has effectively been overwritten by assigning new data to the variable

R variables

• You can get more attributes than just class. The function str gives you the structure of the object.

```
str(x)
```

```
num [1:4] 1 4 6 8
str(y)
```

```
num [1:4] 2 6 9 12
```

This tells you that x is a numeric vector and tells you the length.

Review

- Creating a new script
- Using R as a calculator
- Assigning values to variables
- Performing algebra on numeric variables
